Perioperative care for patients with Nager-de Reynier syndrome (NdRS) is challenging due to the rarity of disease and the lack of consensus on optimal anesthetic management. NdRS is a pre-axial acrofacial dysostosis and as of yet, has uncertain incidence. Given the complex multisystemic nature of the disease with extremely difficult to impossible non-surgical airway, judicious perioperative planning is needed. We present the anesthetic management of a patient with NdRS undergoing oral and maxillofacial surgery.
